

PROJECT DEVELOPMENT PHASE

Project Development

The Farm Management System (FMS) was developed using the Salesforce platform to digitize and streamline agricultural operations. The system manages information related to farms, crops, farmers, and buyers. It also provides reports and dashboards to help users monitor agricultural activities and analyze farm data.

Salesforce Developer Org

A Salesforce Developer Org was created to develop and configure the Farm Management System. The Salesforce environment provides the required platform for creating custom objects, fields, relationships, users, roles, reports, and dashboards.

Custom Objects

Four custom objects were created for the Farm Management System:

- Farm – Stores farm-related information.
- Crop – Stores crop production details.
- Farmer – Stores farmer information.
- Buyer – Stores buyer details.

These objects help organize agricultural data systematically.

Tabs and Lightning App

Custom tabs were created for Farm, Crop, Farmer, and Buyer objects. A Lightning App named Farm Management System was configured with these tabs along with Reports and Dashboards.

This provides a simple navigation interface for accessing different modules of the application.

Fields and Relationships

Fields were created for each custom object to store the required information.

The Farm object includes fields such as Farm Type, Soil Quality, Irrigation Type, Location, and Size.

The Crop object includes Crop Name, Planting Date, Harvest Date, Actual Yield, Total Acres Harvested, and Expected Yield per Acre.

The Farmer object includes Contact Number, State, District, and Village.

The Buyer object includes Contact, Email, Address, and Buyer Type.

Relationships were also configured between the objects to connect related agricultural records.

Profiles and Roles

Profiles and roles were configured to control user permissions and access within the Salesforce application. A Farm Manager profile and role were included as part of the system configuration.

Users and Sharing Rules

Users were created in the Salesforce environment. Sharing rules were configured to provide appropriate record access to users based on the defined requirements.

Reports

Reports were created to display and analyze farm-related information. A Farmer with Farms report was created to display related records. Reports help users view information in an organized format.

Dashboard

A dashboard was created using the generated reports. The dashboard provides visual representation of farm-related information and helps users monitor the system data more easily.

Development Outcome

The completed development provides a centralized Salesforce-based Farm Management System for managing Farm, Crop, Farmer, and Buyer information. The application also includes relationships, access control, reports, and dashboards to support efficient agricultural data management.
